

AI-Powered Order Management System

Build a working AI-powered order management system for an eyewear brand. The system must handle the full order lifecycle, from intake to delivery, with AI assisting at key stages.

Background

An eyewear order is not like a standard e-commerce order. Each order carries a prescription, a lens type, lens index, coating and frame. Orders come from multiple sources.

The fulfilment flow is complex and involves multiple stages from: order placed to delivered. Each lens type has a different SLA. Failures at QC loop back to a re-order.

What to Build

Build all modules below as one integrated system.

Lens Inventory management

Lenses are kept inhouse as well of some coatings and thickness. This is done on past data. Once customer order is placed the system needs to tell if the power is in house or not it delivers it asap.

Status change in every order and dashboard

A dashboard which the team can use to manage every order through all the stages and also showing all active orders, their current status, time remaining against SLA, and any breaches. Filterable by status, lens type, and store location. The team must be able to update the status and log a reason for any delay.

TAT Prediction & Breach Alerts

The system must predict which orders are likely to breach their SLA before it happens and send an alert to the team. Use order history and current stage to drive this. Alerts can be email or WhatsApp.

Deliverables

- **Live deployed system:** Working URL.
- **Demo walkthrough:** 15-minute screen recording or live demo covering all 3 modules.
- **1-page architecture note:** What AI models/APIs you used and why.
